

EPPO Datasheet: *Peach yellows phytoplasma*

Last updated: 2022-07-05

IDENTITY

Preferred name: *Peach yellows phytoplasma*

Taxonomic position: Bacteria: Tenericutes: Mollicutes:

Acholeplasmatales: Acholeplasmataceae

Other scientific names: *Little peach phytoplasma*, *Peach red suture phytoplasma*

Common names: little peach, peach red suture, peach yellows

[view more common names online...](#)

EPPO Categorization: A1 list

[view more categorizations online...](#)

EPPO Code: PHYP29

Notes on taxonomy and nomenclature

Work by Davis *et al.* (2013), employing sequence and computer-simulated RFLP analyses of 16S rDNA, has shown that peach yellows (also called little peach) phytoplasma is to be regarded as the X-disease agent ‘*Candidatus Phytoplasma pruni*’, a member of the X-disease phytoplasma group or 16SrIII group, subgroup 16SrIII-A. Phytoplasmas associated with peach rosette and peach red suture diseases are also regarded as ‘*Candidatus Phytoplasma pruni*’ (Davis *et al.*, 2013).

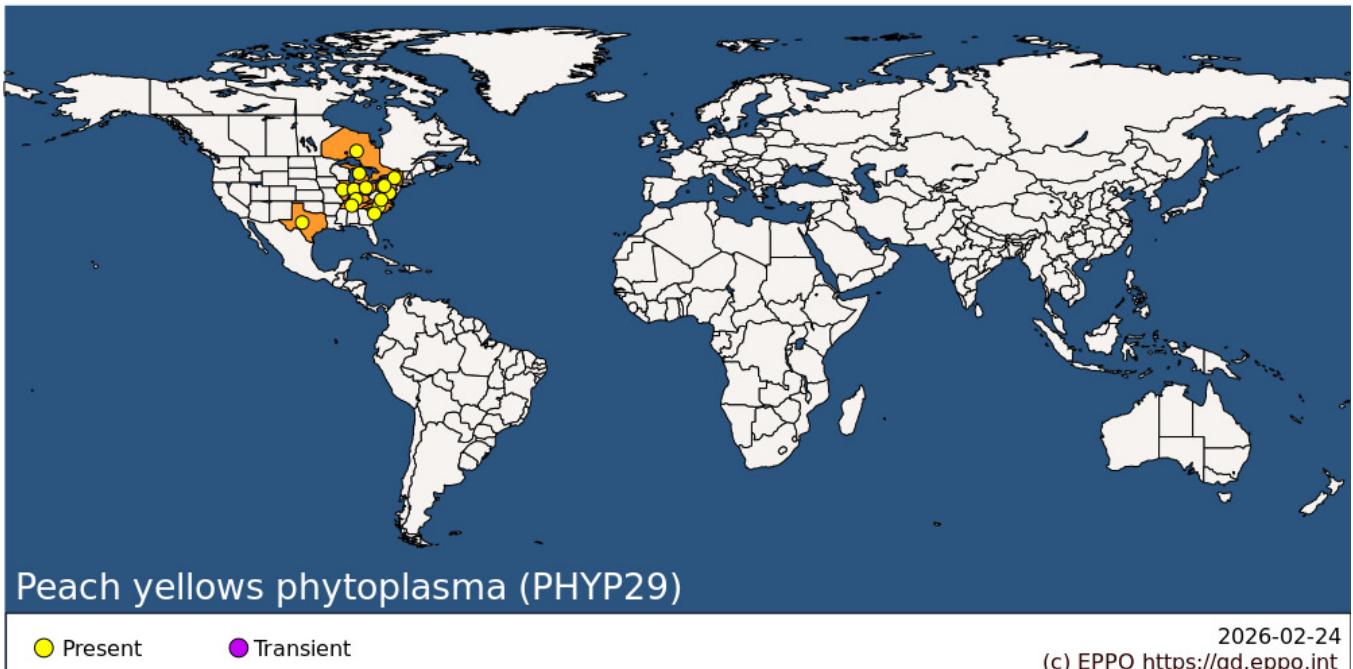

HOSTS

Peach (*Prunus persica*) is the principal host of peach yellows phytoplasma. Almond (*P. dulcis*), apricot (*P. armeniaca*) and Japanese plum (*P. salicina*) are also infected. All *Prunus* spp. which have been experimentally graft-inoculated proved to be susceptible. Peach yellows phytoplasma is symptomless in some cultivars of *P. salicina* such as Abundance, Chalco and Chabot. The phytoplasma can also be artificially transmitted to herbaceous hosts.

Host list: *Prunus armeniaca*, *Prunus dulcis*, *Prunus persica*, *Prunus salicina*, *Prunus*

GEOGRAPHICAL DISTRIBUTION

Peach yellows was first observed in Pennsylvania in 1791 (Kunkel, 1936a). The disease spread gradually northward, through the New England states and into Canada and southward into Delaware, Maryland, Virginia, West Virginia, and North Carolina. Peach yellows has not been found in the far western or southern states or outside USA and Canada. European diseases called peach yellows are either caused by other phytoplasmas or have unknown etiologies (Marcone *et al.*, 2014). Epidemic outbreaks in the United States during the 19th and early 20th centuries caused significant tree losses (Kirkpatrick, 1995). Recently, disease incidence has been low (Scott and Zimmerman, 2001; Kirkpatrick *et al.*, 2011).

North America: Canada (Ontario), United States of America (Illinois, Indiana, Kentucky, Maryland, Michigan, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Virginia)

BIOLOGY

The peach yellows phytoplasma is transmitted by grafting and by the plum leafhopper *Macropsis trimaculata* (Hemiptera: Cicadellidae). It has an incubation period of 1-3 years in trees in orchards but less than 60 days under glasshouse conditions. In the vector, the mean latent period is 16 days (Pine & Gilmer, 1976; Weintraub & Beanland, 2006). Symptoms of peach red suture disease are similar to those of peach yellows. However, attempts to transmit peach red suture disease with the leafhopper *M. trimaculata* have failed.

DETECTION AND IDENTIFICATION

Symptoms

Leaf buds on diseased peach trees, even those that should normally remain dormant, develop prematurely. Leaves produced from these buds are narrower and smaller than normal leaves, and as the season progresses, they become chlorotic and often develop red spots. Affected trees produce slender, branched, willowy shoots that grow upright from the main limbs, thus giving the tree a bushy appearance. Leaves borne on the abnormal shoots are dwarfed, severely chlorotic with the margins rolled upward and drop prematurely. As the disease progresses, diseased limbs dieback and the trees succumb one to five years later. Fruits produced on diseased limbs ripen two to three weeks earlier than healthy fruits. They are of normal size but of low quality, usually with a bitter taste. In red-skinned cultivars, the fruit surface shows highly pigmented spots with red streaks in the flesh and a pronounced red colour around the pit (Dunez, 1981; Kirkpatrick, 1995).

Morphology

Electron microscope studies have shown the presence of typical phytoplasma bodies in sieve tube elements of peach trees exhibiting peach yellows symptoms, and in periwinkle (*Catharanthus roseus*) plants following dodder transmission from peach (Jones *et al.*, 1974a, b). The bodies were often present in very large numbers, they were surrounded by a unit membrane and contained in their cytoplasm, dispersed strands resembling DNA and ribosome granules. They were morphologically indistinguishable from those associated with other phytoplasma diseases.

Detection and inspection methods

The peach yellows phytoplasma can be tested on peach seedlings (cv. Elberta or GF305) in the field, but it takes 4 years for results to be certain. It can also be tested on the same indicators in the glasshouse, symptoms appearing up to 3 months after inoculation. However, for reliable diagnosis, the identity of the infecting phytoplasma should be determined by molecular technologies such as PCR-based methods. Universal phytoplasma primers as well as X-disease group-specific primers have been designed, directed to ribosomal or non-ribosomal DNA sequences. Primers amplifying rDNA sequences are the most extensively used (Hadidi *et al.*, 2011; Bertaccini *et al.*, 2019; Martini *et al.*, 2019). The sensitivity of detection can be increased by nested PCR.

PATHWAYS FOR MOVEMENT

The peach yellows phytoplasma is spread locally by the insect vector whereas the use of infected plant material is responsible for long-distance movement of the pathogen. Abiotic factors are not involved in natural spread of the pathogen.

PEST SIGNIFICANCE

Economic impact

Peach yellows was responsible for serious losses in the USA in the 19th century, when it was the object of classic research by Erwin Smith (who failed, not surprisingly, to establish the nature of the agent) and of some of the first legislative measures against a plant disease (Michigan Yellows Law of 1875) (Ainsworth, 1981). Severe outbreaks continued into the early 20th century but in recent decades the disease has been seen only rarely (Kirkpatrick *et al.*, 2011). Pine & Gilmer (1976) reported that peach yellows disease tended to follow a cyclical pattern in large peach-growing areas. More recently, peach yellows disease affects only a few trees within an orchard in the South-Eastern United States. Symptomatic trees do not emerge from dormancy, and this results in the loss of a few trees with relatively little economic impact. The greatest economic impact in the South-Eastern United States is that budwood from sources on the east coast cannot be exported to states on the west coast because of embargo based on the possible latent presence of this disease and its graft transmissibility (Kirkpatrick *et al.*, 2011).

Control

Infected trees should be destroyed and the insect vector *Macropsis trimaculata* should be controlled. Healthy planting material should be used for establishing new orchards. In this respect, peach yellows was one of the first 'virus-like' diseases to be treated using thermotherapy. The pathogen is eliminated from dormant trees and buds by hot-water treatment at 50°C for 10 and 3-4 min, respectively (Kunkel, 1936b).

Phytosanitary risk

In the EPPO region, peach, the main host, has the greatest economic importance among all *Prunus* spp. There are probably susceptible European cultivars and, in any case, American cultivars are frequently introduced. Though the American vector does not occur in Europe, local insects might act as vectors. Healthy planting material of *Prunus* is recommended, and nuclear stocks should be screened at regular intervals using highly sensitive PCR-based tests. However, this pest is undoubtedly less important than peach X-disease phytoplasma (EPPO/CABI, 1996).

PHYTOSANITARY MEASURES

Prunus planting material should come from a field inspected during the growing season and, particularly for material from infested countries, the material should be subject to an official certification scheme, with particular emphasis on preventing infection of healthy material by the insect vector. The EPPO certification scheme for fruit trees (EPPO, 2001a, b), though intended to be used primarily within the EPPO region, provides a suitable model.
